In a Random Vibration study, the loads are described by Power Spectral Density (PSD) functions. The PSD functions are a measure of a vibration's intensity in the frequency domain. These functions determine the average of the acceleration amplitudes within a certain frequency range, as although acceleration amplitudes at a frequency constantly change, the average value tends to remain relatively constant.

Numerical solutions to free vibration analysis of beams and columns are obtained by the method of differential quadrature (DQ) and harmonic differential quadrature (HDQ) for various support conditions. The obtained results are compared with the existing solutions available from other numerical methods such as finite element method (FEM) and analytical results.
